# Good afternoon folks!✨

# This talk is going to be about a

# Dev Tool

# What kind of Dev Tool?

- One that trainers force us to use!
- One that lets us sleep peacefully at night as a SWE
- One that could *potentially* prevent us from being sued for millions!

One that makes us proud to be at **ThoughtWorks**

# Let's start with a Problem

# /imagine

midjourney, anyone?

# Well....

# !Talisman!

"Keeping your secrets safe"

# Prevention is better than cure

- A tool that installs a **hook** to your git repository to ensure that potential **secrets or sensitive information** do not leave the developer's workstation.

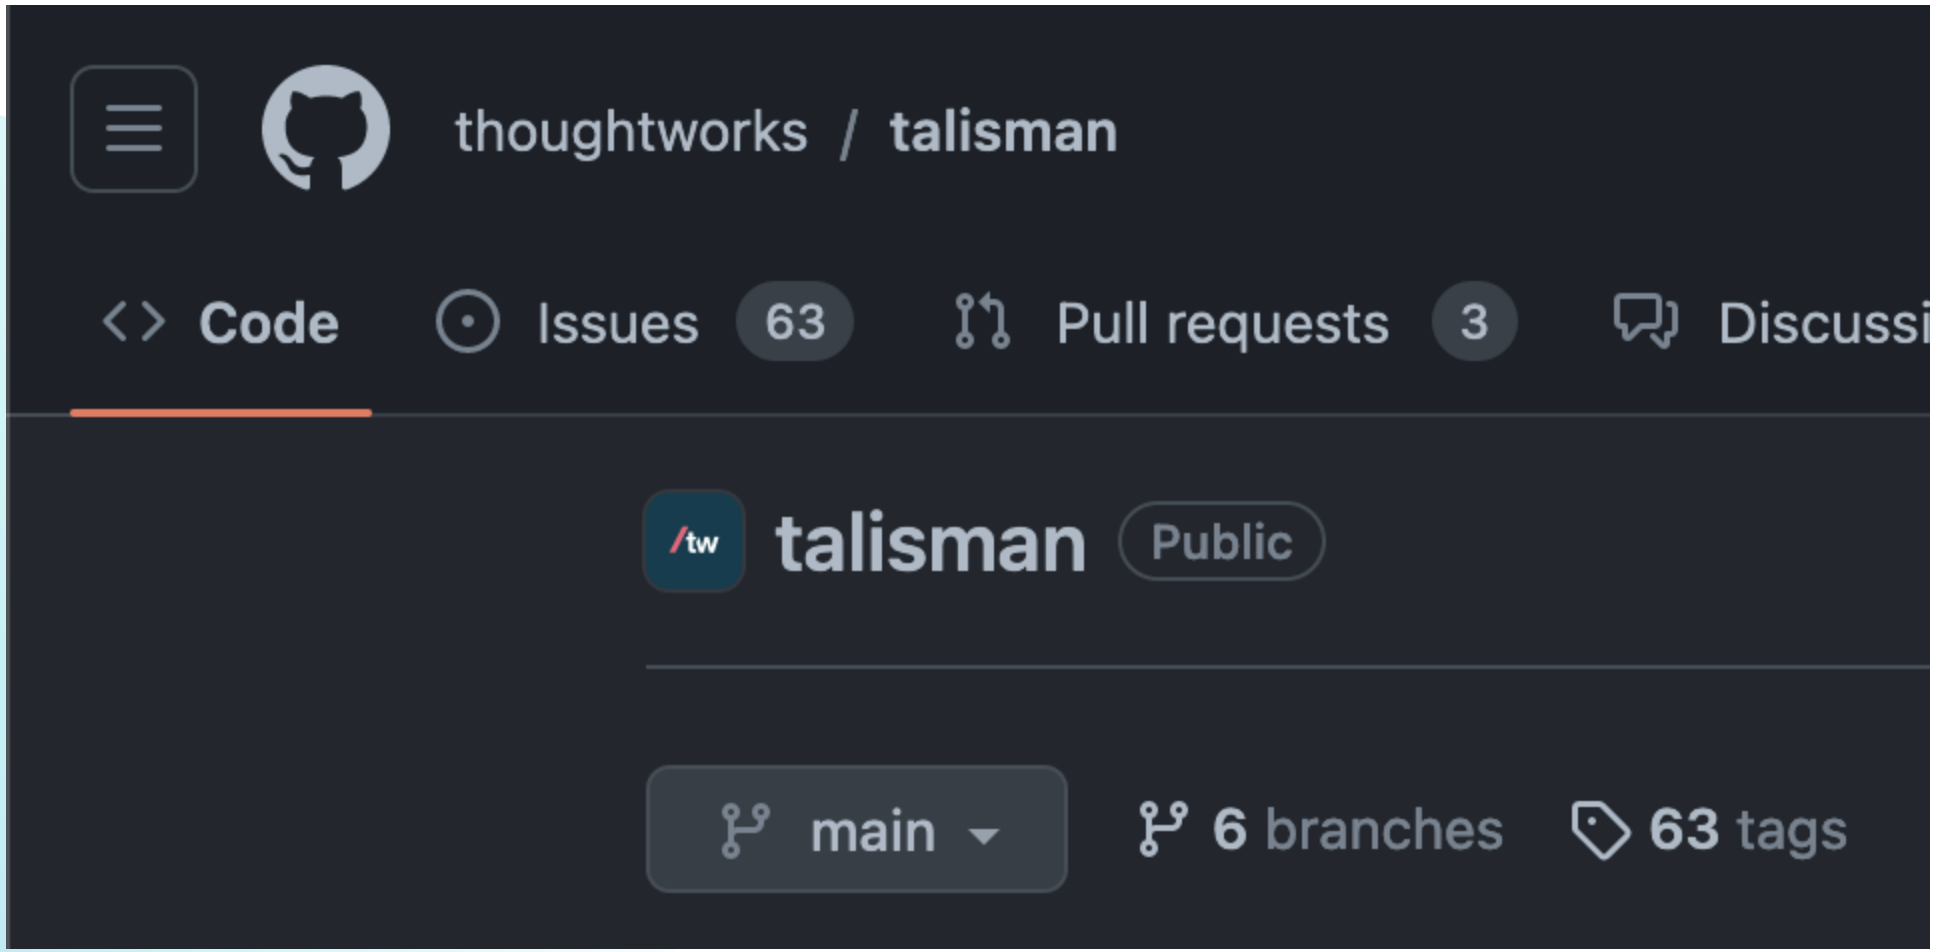

- It validates the outgoing changeset for things that look suspicious - such as potential **SSH keys, authorization tokens, private keys** etc.

# Validation

- **Encoded values** - scans for encoded secrets in Base64, hex etc.
- **File content** - scans for suspicious content in file that could be potential secrets or passwords
- **File size** - scans for large files that may potentially contain keys or other secrets
- **Entropy** - scans for content with high entropy that are likely to contain passwords
- **Credit card numbers** - scans for content that could be potential credit card numbers
- **File names** - scans for file names and extensions that could indicate them potentially containing secrets, such as keys, credentials etc.

You can explore further to add your own custom configurations , such as, checking for custom patterns, set custom thresholds etc.
